

● INSIDOR

We find the story before the coin exists.

How the whole thing works, what the user sees, what runs behind the scenes, and the order we build it in.

PART ONE	PART TWO	PART THREE
The product Every screen, and what a trader actually does with it.	The machinery The six parts that run without anyone pressing anything.	How it comes together Where the line sits, one story end to end, and the build plan.

Contents

PART ONE · THE PRODUCT

01	What Insidor is	The problem with every existing tool, and the one step earlier we work.
02	The narratives feed	The home screen. Seven things per row, and nothing else.
03	The narrative page	The main attraction. Every coin, labelled honestly, plus the thesis layer.
04	Create a coin	Minting the first coin off a story, in a few taps.
05	Trading, watchlist, search, trending	The supporting screens.

PART TWO · THE MACHINERY

06	The six parts of the machine	Collector, Measurer, Judge, Grouper, Library, App.
07	What we build, what we rent	We build the detection. Everything else is plumbing.
08	What we store, and what it costs	The database in plain English, and roughly £5 a day.

PART THREE · HOW IT COMES TOGETHER

09	Where the line sits	Facts go on screen. Our reasoning never does.
10	One story, end to end	The ferry captain, from 9:00am to 34 minutes ahead.
11	The build plan	Eight stages, and the one thing that has to be true first.

PART ONE

The product

What a trader sees and does. Every screen in this part shows facts about the world and nothing about how we decided.

-
- 01 What Insidor is
 - 02 The narratives feed
 - 03 The narrative page
 - 04 Create a coin
 - 05 Trading, watchlist, search, trending

01. What Insidor is

Memecoins are made out of things going viral. Every tool a trader uses today shows them a coin only after it exists and money is already moving into it. Insidor works one step earlier: we watch the internet, not the money, and show people the story before anyone has made a coin out of it.

The problem

Axiom, Photon and GMGN are all screens full of coins. They are good screens. But a coin can only appear on them once somebody has already created it, and by then the interesting part has happened. The first buyers are in. The chart already has a shape. What you are looking at is not an opportunity, it is the aftermath of one.

That has a blunt consequence. If you are consistently arriving after the coin exists, you are not early — you are the person the early buyers sell to. Being fast on those tools only makes you the quickest of the late.

The idea

Every one of those coins started as something on the internet: a clip, a photo, a sentence that made a lot of people laugh at the same time. That thing is public, it is free to look at, and it exists **before** the coin does. So instead of watching the money, we watch the thing the money will eventually chase. We scan social media, spot posts that are exploding right now, and put them in front of traders while there is still nothing to buy.

One story, one clock. Everyone else's product begins at 09:47, where the coin already exists. Ours begins at 09:13, where there is only a video of a ferry. The 34 minutes in between is the entire company.

Two ways to win

Arriving that early leaves the user with two moves, and Insidor supports both in the same place. That matters: nobody wants to spot a story here, then go somewhere else to act on it.

A NO COIN EXISTS YET

They create it themselves, in one tap

The story is climbing and nothing has been minted off it. The user makes the coin from inside Insidor and is first in — not first to buy, first to exist.

09:31 · a user mints \$FERRY

crypto Twitter notices at 09:47

B A COIN ALREADY EXISTS

They buy it in the same app, still early

Someone beat them to minting by a few minutes. They still saw the story before the rest of the market did, so they buy it here without leaving the page.

Plastic Plant Grandma · \$PLANT

850K views · 2h old · \$562.8K market cap

Why it is defensible

Speed alone is not a moat — anyone can build something fast. What protects Insidor is that two assets get bigger every day the product runs, and a competitor starting tomorrow starts with none of either.

COMPOUND #1 · THE COMMUNITY

Their thesis history lives here

Traders post their reasoning on each story — why this one is real, why that one is nothing. Over months that becomes a public track record with their name on it.

People do not abandon a reputation they spent a year building. The writing is the lock-in, and we are not the ones who have to produce it.

COMPOUND #2 · THE RECORD

Which viral posts became coins that made money

Every story we surface, we keep: what it looked like as it climbed, whether a coin followed, and how that coin did. Nobody sells this. You cannot go back and ask what a post looked like twenty minutes ago — if it was not recorded live, it is gone.

A competitor can copy the screen in a fortnight. They cannot copy a year of yesterdays.

Who this is for

THE TRADER

Wants to be first, not fast

Already good at reading a chart, already has Axiom open. What they do not have is anything that fires before the chart exists. That is the only thing we sell them.

THE CREATOR

Wants to mint off a meme

Their whole job is finding the funny thing early. Today that means scrolling all day and hoping. Here the candidates arrive already sorted, with a name and ticker suggested.

THE NEWCOMER

Saw it on TikTok, wants in

No wallet, no jargon, no idea what a bonding curve is. They get a page that explains the story in one sentence and a button that works. Everything else stays out of the way.

Three people, one screen. The trader reads it for the timing, the creator for the raw material, the newcomer for the sentence at the top. Nothing on the page is written for an insider only.

02. The narratives feed

The home screen. A single list of the stories going viral on the internet right now, best one at the top, each one explained in two lines of plain English so you never have to watch the video to know what it is.

Every other tool a trader opens — Axiom, Photon, GMGN — is a list of coins. Insidor's home screen is a list of **stories**, and most of them do not have a coin yet. That is the whole point. If a row already has money flowing into it, you were late. The feed's job is to put the ferry captain in front of you at 09:13, eighteen minutes before anybody turns it into a coin called \$FERRY and thirty-four minutes before crypto Twitter notices.

The order of the list is the product. Behind it sits everything described in section 01 — how fast views are climbing, how many separate people are posting the same thing, whether the AI thinks a coin could plausibly be made out of it. **None of that appears on screen.** The user gets the order; the order *is* the answer. Putting our numbers next to the rows would hand the judgement back to the person we are meant to be making it for.

The two lines are the product

The most important text in the whole app is the sentence under each title. "A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back." Read that and you already know whether it is worth a coin — you can feel whether it is funny, whether it has a name in it, whether people will repeat it. So it is set larger and brighter than the title above it. It is not a subtitle. It is the row.

Everything else on the row is a fact about the world that would be true whether or not Insidor existed: how many people have seen it, whether the line is still going up, how old it is, and what you can do about it. Seven things, no eighth.

SIX ROWS, SEVEN ELEMENTS EACH, NOTHING ELSE. NOTE ROW 3 SITTING ABOVE ROW 4: 850K VIEWS RANKED ABOVE 1.1M. THE LIST IS NOT SORTED BY VIEWS — THE 850K IS TWO HOURS OLD AND STILL CLIMBING, THE 1.1M IS SIX HOURS OLD AND FLAT. THE USER IS NOT TOLD WHY. THEY SEE THE ORDER, AND THE TWO LITTLE LINE GRAPHS QUIETLY AGREE WITH IT.

The seven elements, and why each one earns its place

- 1

A picture from the post

The still frame from the video or image. It is how you recognise a story you have already seen scrolling elsewhere, in a fifth of a second, before reading anything.
- 3

Two lines of plain English

The point of the entire screen. You should understand the story without watching the video. Largest, brightest text in the row — it is what you actually judge the trade on.
- 5

A tiny line graph

The view count over the last hour. Answers the one question a single number cannot: is it still going up, or is it over? Cyan and rising, or grey and flat.
- 7

One button

Create coin if nobody has made one, Buy \$TICKER if somebody has, 3 coins → if several exist and you need to pick. One row, one obvious next move.

- 2

A title

"Harbor Last Horn." A short handle so the story can be referred to, searched for, and pasted into a group chat. Deliberately set smaller than the sentence below it.
- 4

How many views

The headline number, big and unambiguous. A true fact about the world: this many people have seen it. Not our estimate of anything, just the count.
- 6

How old it is

Four hours. Six hours. Combined with the graph this is the whole timing story — 850K in two hours is a different animal from 850K in two days.

What we removed, and where it went

An earlier version of this screen showed the row as a trading terminal: columns headed HEAT, ACCEL, ORG and MEME, a twenty-minute chart of view-rate change, and a footer counting how many posts our filters had thrown away. Every number on it was real. It still had to go, because it asks the user to do the job we built the company to do for them.

×

REJECTED — OUR WORKINGS ON THE USER'S SCREEN

Everything struck through is an internal number. It exists. It never appears.

3 coins →

SAME STORY, SAME SECOND, SAME UNDERLYING DATA. THE TOP ROW ASKS THE READER TO WEIGH UP SIX NUMBERS AND DECIDE. THE BOTTOM ROW HAS ALREADY DECIDED, AND SAYS SO BY SITTING AT THE TOP OF THE LIST. NOTE THAT VIEWS, AGE AND THE ACTION SURVIVE THE CUT — THOSE ARE FACTS, NOT OPINIONS.

To be completely clear: **we still calculate every one of those numbers.** They are what decides the order of the feed, which stories get grouped together, and which of the hundreds of millions of daily posts we bother looking at twice. They are written into the Library on every cycle and they are what section 07 will eventually learn from. They simply never leave the building.

INTERNAL NUMBER	WHAT IT DECIDES	WHERE IT LIVES
heat	How high up the feed a story sits right now.	Library → row order only
acceleration	Whether a story is still climbing or has peaked, from two measurements of the same post.	Library → row order only
organic score	Whether the attention looks like real people or like a paid push.	Library → included / excluded
meme score	The AI's read on whether a coin could plausibly be made out of this at all.	Library → included / excluded
eligibility gate	How many candidates were dropped before the list was built.	Library → never surfaced

03. The narrative page

The screen the whole product is built around. One story, one page: what happened, how big it is now, which coins were made from it, where to buy, and what other traders think.

Every narrative gets its own web address — `insidor.app/n/harbor-last-horn` . A trader pastes that link into a group chat, and someone who has never heard of us opens it, understands the story in one sentence, and can act. Nothing on it needs an account to read. The page is the marketing.

It answers four questions in one place: **what is this** · **is it still hot** · **which coin is the real one** · **what do other traders think**. Today those answers live in four separate tabs — a video app, a chart, a token scanner, a group chat. Putting them on one page is most of the product.

The story, and how viral it is

The top of the page is the clip and the plain-English two-liner. That sentence is the most important text in the product — it is what a stranger reads first. Beside it sit facts only: views, reposts, likes, age, and the view counts we recorded ourselves as the story grew. Nobody sells "what did this post look like twenty minutes ago", so we write it down as it happens and show it back plainly.

Kristiansund, Norway · 09:00 today

A BIT MORE, FROM THE POSTS

Captain Bjørn Hagen finished his last shift on the Kristiansund route this morning after 41 years. He sounded the horn leaving the quay; six vessels in the harbour answered, then the pilot boat, then the lifeboat station. Filmed from the pier by a passenger, posted forty minutes later.

SECOND CLIP IN THIS STORY

@harbourclips on TikTok · 890,000 views · posted 09:12

Coins made from this story3 found · first one made at 09:31, 31 minutes after the post

COIN	PRICE	1H	MARKET CAP	LIQUIDITY	HOLDERS	
FIRST \$FERRY Harbor Ferry · made 09:31	\$0.0007996	+42.8%	\$799.6K	\$88.4K	1,204	Buy \$FERRY
BIGGEST \$HORN Last Horn · made 09:38	\$0.0012040	+18.2%	\$1.20M	\$141.2K	2,867	Buy \$HORN
UNVERIFIED \$BOAT Boat Horn · made 11:52	\$0.0000431	-9.4%	\$43.1K	\$6.2K	87	No buy button on this one

Why no button on \$BOAT.

We are not sure this coin belongs to this story. It might; it might be riding a different one. We would rather show it and say so than hide it, and rather leave the button off than help you buy something we cannot stand behind. You can still open it on any explorer.

Every number here is a fact about the world — views, reposts, likes, market cap, liquidity, holders, times. Our judgement shows up in what we chose to put on the page, never in a number printed next to it.

Why every coin is listed, not just one

When something goes viral, several people make a coin within minutes. One is the real one the crowd settles on; the rest are copycats riding the attention. Showing only "the coin" would mean a user sometimes buys a copycat and loses money because of a silent decision of ours. So we list all of them, labelled: **First** — made from this story before any other. **Biggest** — the most money in it now. Those are usually different coins, and which one you want depends on how you trade.

The third label matters most. **Unverified** means we think a coin relates to this story but we are not confident, and it gets no buy button at all — not a greyed-out one. In the founder's words: *"A greyed-out button looks like something we're holding back; no button at all is us not making a claim we can't stand behind."*

Trading and research, on the same page

Buying happens here, not in another app — and we rent the exchange rather than build it. The plan is to route orders through **Axiom** or **Photon**, pending confirmation they permit it; neither publishes a public developer interface today, so the confirmed fallback is **Jupiter**, which works now and pays us a fee for the business. Wallets are handled by **Privy**; charts, safety checks and holder data by DexScreener, RugCheck and Helius. All plumbing. What we build is the part above — finding the story before the coin existed.

Four posts, one story. The list is here so a user can check us with their own eyes: read the posts, decide whether they really are the same thing. Evidence, not arithmetic.

The thesis layer

At the bottom, traders write what they think. Two facts attach automatically at the moment of posting and can never be edited: **how big the story was when they said it**, and **whether they own the coin** — holding, sold, or no position, read from the connected wallet. Someone who called this at 340,000 views reads very differently from someone who turned up at 2.4 million; someone talking up a coin they hold reads differently from someone with nothing on the table. Neither is disqualifying. Both are things you would want to know.

Holding \$FERRY

09:44 · 3H AGO

Nordic maritime nostalgia travels further than people think — this is the same shape as every "old man does a last shift" clip that ran for days. Every boat answering back is the bit that makes it a meme rather than a news story. I took a position on \$FERRY because it was first and the name is the obvious one.

Sorted by most useful · every take shows the two attached facts, always

The two pills beside each name are the whole point: the story's size and the wallet's holdings, both frozen at the moment the take was posted.

Why nobody else can build this layer

It looks like a comment section. It is not, because of who can attach those two facts. Twitter knows what people say but not what they own. A trading app knows what they own but not what they think. Insidor is the only place the take and the wallet arrive together, on the same story, at the same moment — so the record writes itself and compounds. That history is why traders stay: their calls and their reputation live here.

The same argument as the view-count history: the only way to have it is to have been recording since day one.

What is deliberately not on this page

None of our own scoring. No heat number, no acceleration figure, no confidence percentage on the unverified coin. The page carries facts about the world and our decisions — which story to show, which coins to list, which one gets a button. The user gets the judgement, not the arithmetic.

04. Create a coin

Every other tool shows a coin after it exists. We show the story before it exists — so we can offer something nobody else can: the user makes the coin themselves, from the story, in a few taps, and is first in.

This is the single biggest thing that separates Insidor from Axiom, Photon or GMGN. Those tools are fed by money moving. A coin has to already be trading before it can appear on them, which means every user of those tools arrives after somebody else got there. We are fed by the internet instead, so we see the ferry captain, the plastic plant, the town paying people to move — while the coin is still an idea. At that moment the user has two doors. If a coin exists, they buy it (section 03). If none does, they open this sheet.

The example here is **"Paid to Move to Norway"** — a Norwegian town is paying people €25,000 to move there. 1.1M views, an hour old, and nobody has made a coin out of it yet.

Where the pre-filled name comes from

The user does not sit and think of a name. The work was already done, about an hour earlier, by a part of the system they never see. When our AI reader looked at this post it was answering one question — could someone realistically make a memecoin out of this? — and part of answering it is proposing what the coin would be called. That suggestion was written down at the time and stored with the story. By the time somebody taps *Create*, the name, the ticker and the image have been sitting there ready for an hour.

The whole left half of this line happens without anybody asking for it. Naming is a by-product of judging, so it costs nothing extra and it is finished long before a human arrives.

The create sheet

One screen. The story sits at the top so the user can see what they are minting. Everything below it is pre-filled and everything is editable. Nothing here is a decision the user has to research — it is a decision they either accept or nudge.

Create the coin

A Norwegian town is paying people €25,000 to move there.

Insidor never holds your money or your keys. We prepare the transaction; you approve it in your own wallet on the next screen.

THE STORY IS LOCKED TO THE TOP

So it is always obvious what this coin is *of*. The two-line summary is the same sentence the user read in the feed — no re-writing, no surprises.

NAME AND TICKER ARRIVE FILLED IN

Written an hour ago when the AI judged the post. Tapping *Edit* replaces them with anything the user prefers; the alternatives are one tap away.

AVAILABILITY IS A LIVE CHECK, NOT A GUESS

We ask pump.fun whether the ticker is taken before the user commits. \$25K is struck through because somebody already used it.

THE IMAGE IS A STILL FROM THE POST

Three alternate frames plus an upload slot. Most users will accept the first one, which is the point.

THE FIRST BUY IS OPTIONAL AND HONEST

It says exactly what 1 SOL gets you and what share of the coin that is. Turning the toggle off drops the total to 0.0202 SOL.

ONE NUMBER, IN POUNDS

Crypto interfaces habitually show a total the user has to convert in their head. We show SOL and sterling, and we say plainly that we charge nothing at this step.

HOW WE ACTUALLY GET PAID

A cut of trades afterwards, smaller than the creator's. Stated on the screen where it applies rather than buried in terms.

Nothing on this sheet is a number we invented about the story. Views, age, who posted it, the cost, the fee split, the share of supply – all facts the user could verify elsewhere. The judgement that put this story in front of them stays behind the curtain.

When the ticker is not available

Tickers are first-come. Checking after the user has signed something would be a bad experience, so the check runs while they are still looking at the field.

WHILE WE CHECK

\$NORWAY

Half a second, usually. The [Review in wallet](#) button waits rather than letting the user run ahead.

FREE

\$NORWAY

AVAILABLE

Nothing further to do. **Carry on.**

ALREADY USED

\$25K

TAKEN

\$25K already exists on pump.fun. Pick another, or open the one that exists.

The taken state offers a way out, not just a refusal – if a coin with that ticker already exists we can show it, and the user may decide buying it is the better move.

Signing it

This step is where the safety promise is kept. Insidor builds the transaction and hands it to the user's wallet. The wallet — provided by Privy, so that the specialist handles the hard part — shows what is about to happen and asks for approval. We never take custody of funds and we never see a private key. If the user rejects it, nothing happens and nothing has been spent.

The success state does one job beyond confirming: it hands over the shareable link. The story page now lists \$NORWAY, so anyone the user sends it to lands on the narrative — not on a chart of a coin they have never heard of.

What we build here, and what we rent

PIECE	WHO DOES IT	WHY
Knowing this story has no coin yet	Insidor	The entire reason this screen can exist. Nobody else is looking before the money moves.
The suggested name, ticker and image	Insidor, via Claude	Produced as a by-product of judging the post an hour earlier.
Checking the ticker is free	pump.fun	They hold the register, so we ask them.
Creating the coin	pump.fun	The standard every trader already uses. Building our own launcher would win us nothing.
Holding the wallet and signing	Privy, on the user's device	Custody is specialist and dangerous. We stay out of it entirely.

Same rule as everywhere else: we build the detection, we rent the plumbing. The only irreplaceable part of this screen is knowing there was something worth minting an hour before anyone else did.

05. Trading, watchlist, search and trending

Four supporting features. None of them is the reason someone opens Insidor, but without them the person who spots a story early has to leave to act on it, forgets to come back, accidentally makes a coin that already exists, or can only see what we choose to push at them.

Trading — buying built into the page

When a narrative already has a coin, the buy box sits on the same page as the story. No copying a contract address into another app, no second tab, no losing the thing you were looking at. You read the two-liner, you look at the numbers, you buy. We take a small fee on every trade that goes through us, and that fee is shown in the order before you confirm — nothing hidden in the price.

We do not build the trading engine. Actually executing a trade on-chain — routing it, getting a good price, handling failures, not losing people's money — is hard, risky, and already solved by companies who do only that. **The plan is to route orders through Axiom or Photon, pending confirmation that they permit it: research found neither publishes a public developer API, so the integration is not yet proven.** The confirmed fallback is Jupiter, which is openly documented and pays us an integrator fee, where Photon charges the user 1% and pays us nothing.

NARRATIVE

Harbor Last Horn

A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back.

Order routed to Axiom · wallet by Privy
Jupiter used if routing is unavailable

Everything on this panel is a fact you could check elsewhere: price, market cap, liquidity, holder count, the time the coin was made, the fee we charge. The routing line names who executes the trade and who holds the wallet, because the user is entitled to know whose hands their money passes through.

Watchlist — the notification is the feature

Saving a narrative is easy to build and easy to ignore. The part that matters is what happens after: if a narrative you saved gets its *first* coin, we tell you within seconds. That is the whole retention mechanic. Instead of hoping the user remembers to check back, we open the app for them at the one moment there is actually something to do — a story they already believed in has just become tradeable, and almost nobody else knows yet.

The alert only fires on events worth waking someone for: a first coin on a saved narrative, or a new post joining a saved narrative. Not price moves, not daily digests. If we send noise, the user turns notifications off and the mechanic dies.

The notification carries the two-liner, not a ticker on its own — the user saved a story, so remind them which story. Tapping it lands on the coin with a buy button already there, two taps from lock screen to trade.

Search — one box, and it stops duplicates

One field takes three kinds of input: a keyword (“ferry”), a ticker (\$FERRY), or a coin address pasted from anywhere. It returns both sides at once — the posts and narratives we are tracking, and the coins that exist. Its most useful job is unglamorous: a trader sees something funny on X, wants to make a coin out of it, searches, and finds three already exist. That one screen stops a lot of wasted money.

● Three coins already exist for this story.

Check them before you make a new one.

Coin addresses are shown truncated but are the real thing, and each coin says which narrative it belongs to and when it was made. The amber line at the bottom is the duplicate warning — a statement about the world, not an opinion about it.

Trending — letting people browse

The feed shows what we think is worth seeing right now. Trending lets someone ignore that and look for themselves: the top narratives and the top coins, sorted by views or by age, newest first or biggest first. It is the release valve for anyone who does not want to be led — and the sort controls are the user’s, not ours.

Top narratives			VIEWS	AGE	Top coins			MARKET CAP	AGE
01		Harbor Last Horn 4h · 3 coins	2.4M	views	01		\$HORN Harbor Last Horn · 3h	\$1.2M	-4.1% 1h
02		Paid to Move to Norway 1h · NO COIN YET	1.1M	views	02		\$FERRY Harbor Last Horn · 4h	\$799.6K	+18.4% 1h
03		Grandmaster vs Pigeon 6h · 1 coin	1.1M	views	03		\$PIGEON Grandmaster vs Pigeon · 5h	\$753.5K	+9.7% 1h
04		Plastic Plant Grandma 2h · 1 coin	850K	views	04		\$PLANT Plastic Plant Grandma · 2h	\$562.8K	+6.2% 1h
05		Barista Name Lock-In 3h · NO COIN YET	610K	views	05		\$BOAT Harbor Last Horn · 1h	\$61.4K	+2.9% 1h

Two lists, two sort controls each, nothing else. The ordering follows the column the user picked – views or age on the left, market cap or age on the right – so the ranking is something they can check against reality rather than something they have to trust us about.

All four features lean on things we rent rather than build: Privy holds the wallet, Axiom or Photon (or Jupiter) executes the trade, DexScreener supplies price and liquidity, and the phone's own notification system delivers the alert. What is ours is the moment each one fires — knowing that a saved story just got its first coin, and that this is worth interrupting someone for.

PART TWO

The machinery

The six parts that run on a schedule, without anyone pressing anything.
None of this is ever visible to a user.

-
- 06 The six parts of the machine
 - 07 What we build, what we rent
 - 08 What we store, and what it costs

06. The six parts of the machine

Everything behind the app is six moving parts. Four of them run on their own, on a schedule, with nobody watching. One is a database in the middle. The last one is the app itself. This section is the part of Insidor the user never sees.

The job the machine has to do is narrow: find a post that is going viral right now, work out whether anyone could make a memecoin out of it, and notice when lots of separate posts are all about the same thing. Everything else — the prices, the charts, the wallet, the buying — is rented from companies who already do it well. So the machine is small on purpose. Six parts, and only two of them are things nobody else can do for us.

They pass work along a line. The **Collector** brings in candidate posts. The **Measurer** watches those posts over time. The **Judge** reads the ones that are moving fastest. The **Grouper** bundles related ones together into a single story. All four write what they find into the **Library**, which is one database and the single source of truth. The **App** only ever reads out of the Library. It never talks to X, or to Claude, or to the data reseller directly.

checked.

This sounds trivial and it is the whole product. Here is why. A single view count tells you almost nothing. Five hundred thousand views could mean the post exploded in ten minutes — in which case it is happening right now and you want in — or that it crawled to the same number over two days, in which case it is finished and everyone who cared already saw it. The number on the post is identical in both cases. Only by measuring the *same post twice* can you tell the difference.

Both posts hit exactly 500,000. A tool that reads the number once cannot tell them apart. The difference only exists in the gap between two readings — and that gap is what the Measurer is manufacturing, five minutes at a time.

WHY THIS IS URGENT

This history cannot be bought later. Nobody sells "what did this post look like twenty minutes ago."

You can buy today's view count from a dozen places. You cannot buy the shape of how it got there, because nobody was writing it down. If we are not recording it as it happens, it is gone forever — and every day we run, the record gets longer and a competitor starting tomorrow starts with none of it.

3 • The Judge

Claude reads the posts that are climbing fastest and answers one question: could someone realistically make a memecoin out of this? Most viral posts are useless to us. Politics, sport, a plane crash, a news bulletin — huge numbers, nothing to name a coin after. What works is one absurd thing that has a name: a frog called Gerald, a plastic plant, a ferry horn. When the answer is yes, the Judge also proposes a coin name and a ticker. Understanding humour is exactly the sort of thing a language model is for, and exactly the sort of thing a rule you write by hand will never do.

4 • The Grouper

One person posting a video of a Norwegian ferry captain is luck. Twenty people independently posting about the same captain, on two different platforms, within an hour, is a meme actually forming. The Grouper spots that ten separate posts are about the same thing and bundles them into one **narrative** — which is the unit the whole app is built around. Without it the feed is ten near-identical rows about a ferry. With it, there is one story with ten pieces of evidence behind it.

5 • The Library, and 6 • The App

The Library is one database. Everything the four jobs learn goes in there and nowhere else, which means there is never a question of which copy is right. The App reads narratives out of it and puts them on screen. That is the only direction data moves: the App never reaches out to a social network or an AI itself, so a slow reseller or a failed AI call can never make the page hang.

Where all of this lives

The first four are not something anyone runs. They are scheduled jobs on a server: they fire on a timetable, whether or not our laptops are open, whether or not anyone is using the app. Nobody presses anything. If one fails it retries on its next turn, and the Library keeps whatever it already wrote.

PART	HOW OFTEN IT RUNS	WHAT IT LEAVES BEHIND IN THE LIBRARY
The Collector	every 2 minutes	New candidate posts — who posted, when, on which platform, first view count.
The Measurer	every 2 minutes, first 6 hours	One dated reading per post per check. The only part of the record that can never be recovered later.
The Judge	every 5 minutes	For the fastest movers: a plain-English two-liner, a suggested coin name and ticker.
The Grouper	every 5 minutes	Narratives — which posts belong to the same story, and which coins came out of it.
The App	on demand, when someone opens it	Nothing, except what users themselves add: comments, watchlists, coins they created.

Two-minute checks are the floor, not the ceiling of ambition — a post that goes from 41,000 to 118,000 views between two checks is invisible to anyone sampling once an hour. The cost of running all of this is roughly £5 a day, with a hard cap that pauses collection rather than quietly running up a bill.

07. What we build, what we rent

One sentence carries this whole section: **we build the detection, we rent everything else.** Almost every moving part of Insidor already exists as a service somebody else runs better than we would. We pay for those and spend all of our own effort on the one thing nobody sells.

A small team's only real asset is where it points its attention. Every week spent writing a wallet system, a price chart or a trading engine is a week not spent on the reason the product exists. All of those things are solved problems with mature providers behind them; the thing we are trying to do — see a story going viral *before* a coin is made out of it — is not sold by anyone, because nobody else is recording it.

So the rule for every job in the system is the same question: **can we buy this?** If yes, we buy it and move on. If no, that is where the company lives.

The jobs, and who does them

THE JOB	WHO DOES IT	WHY WE DO NOT BUILD IT
Reading social posts	A data reseller	Buying direct access to the platform costs tens of thousands of pounds a month. A reseller sells the same posts for a few pounds a day. Same data, two orders of magnitude cheaper.
Judging whether a story could become a coin	Claude	Deciding whether a frog called Gerald is funny is a judgement about humour and human attention. Understanding that is precisely what a language model is for, and writing our own would take years.
Buying and selling	Axiom or Photon fallback: Jupiter CONFIRMATION PENDING	Routing a trade well — finding the best price across venues, handling failures, not losing anyone's money — is a business in its own right. Traders already trust these names. See the note below.
Creating coins	pump.fun	It is the standard everyone in this market already uses. A coin made anywhere else looks wrong to the buyers we want, so being different here costs us rather than helps us.
Connecting a wallet	Privy	Holding and protecting the keys to someone's money is specialist, high-consequence work. Getting it 99% right is the same as getting it wrong.
Prices, charts and safety checks	DexScreener · Helius · RugCheck	Standard, freely available, and identical for everyone. There is no version of a price chart that only we could build.
WHAT WE BUILD OURSELVES		
Finding the viral post before the coin exists	Insidor	Nobody sells "what did this post look like twenty minutes ago". The only way to have it is to have been measuring at the time.
Grouping posts into one narrative	Insidor	One person posting is luck. Twenty people independently posting about the same ferry captain is a meme forming — and seeing that requires our own record.

Six rented jobs, two built ones. The two at the bottom are the entire company; everything above them is plumbing.

The same thing as a picture

Look at how small the cyan box is. That is deliberate: six of the eight jobs in the product are somebody else's, so nearly all of our building time goes into the two that are not.

Why the rented parts are not a risk

The usual worry about renting is dependence — what happens when a supplier raises its price or shuts the door? The answer is that every rented job here has at least two credible providers, and swapping one is a few days of work because none of them touch the part that makes us valuable. Our record of viral posts stays ours whichever wallet or chart provider is plugged in.

IF THE DATA RESELLER GOES AWAY

Several competitors sell the same feed. We change one supplier and keep collecting. Time to swap: ~2 days

IF A TRADING VENUE SAYS NO

Jupiter is already confirmed and working. The trade button changes where it points; nothing else moves. Time to swap: ~3 days

IF OUR OWN DETECTION IS WRONG

There is no supplier to call. This is the one failure we cannot buy our way out of — which is exactly why Stage 0 tests it first. Unrecoverable

The only genuinely dangerous box on the page is the one we own. Everything rented has a second option behind it.

An honest note on trading

STATED PLAINLY, BECAUSE THIS ONE IS NOT SETTLED

The plan is to route trades through **Axiom or Photon**, pending confirmation that they permit it — and that confirmation has not been given. Research found neither publishes a public developer interface: Axiom's own documentation index has zero developer entries, and QuickNode's directory states outright that Photon does not support integrations of this kind.

The working alternative is **Jupiter**, which is confirmed, open, and pays us an integrator fee — where Photon charges the user 1% and pays us nothing. So Axiom or Photon is the plan; Jupiter is the fallback that already works, and the product is designed so that either can sit behind the same button.

The point of this section is the shape, not the supplier list. We are building one thing and paying other people to do six. If a reviewer wants to know what Insidor actually is, it is the cyan box: **finding the viral post before the coin exists, and grouping it into a narrative**. That is the company. Everything else is plumbing we rent.

08. What we store, and what it costs

Six kinds of thing get written down, and the whole machine runs on about five pounds a day. This section is the honest accounting: what sits in the database, why each piece has to be there, and where every pound goes.

The database — the Library, part five of the machine — is one central store and the single source of truth. Everything else reads from it. There are six kinds of record. **Narratives** are the stories themselves: one entry per viral moment, holding the plain-English two-liner and the pointers to everything else. **Posts** are the individual social posts that make up a story — the original X post, the TikTok clip someone else put up twenty minutes later. **View readings** are the important one: every single time the Measurer re-checked a post, we write down the clock time and the view count. That is what draws the climbing line, and it is the one thing we could never buy back later. Nobody sells "what did this post look like twenty minutes ago". If we are not recording it as it happens, it is gone.

Coins are every coin we have tied to a story, with a note of how sure we are about the link — some are obvious, some are a guess, and we keep the difference. **Comments** are the traders' theses, each one stamped with how big the story was at the moment it was written, frozen permanently so a call made early can never be quietly reframed as a call made late. **Running costs** are the day's spending on data and AI, written down as we go, so the system knows what it has spent and can stop itself.

THE SIX THINGS WE WRITE DOWN			VOLUMES ARE A NORMAL DAY AT LAUNCH SCALE
WHAT WE STORE	ONE ENTRY IS	FOR "HARBOR LAST HORN"	NEW A DAY
Narratives THE STORY	One viral story, with the two-liner a human reads first.	"A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back."	30 ENTRIES
Posts THE SOURCES	One social post belonging to a story — who posted it, where, and when.	@nordkyst_ferge · X · 09:00 @harbourclips · TikTok · 09:12	1,200 ENTRIES
View readings THE HISTORY	One re-check of one post: the time, and the view count at that time. Never overwritten.	09:04 → 41,000 09:09 → 118,000 09:14 → 264,000 ...	25,000 READINGS
Coins THE MARKET	One coin linked to a story, plus how confident we are in the link.	\$FERRY · first · 09:31 \$HORN · biggest \$BOAT · unverified	50 LINKS
Comments THE THESES	One trader's written call, with the story's size at that moment frozen in.	12 comments earliest stamped "\$0 · no coin yet"	140 COMMENTS
Running costs THE METER	What we have spent today, per supplier, updated as each request is made.	not per story — one line per supplier per day	2 LINES

View readings dwarf everything else — twenty-five thousand a day against thirty stories. That is correct. The readings are the asset; the story is just the label on them.

Forty-one readings for one story. Delete them and you still know the ferry captain went viral — you just can no longer tell whether he was climbing at 09:09.

The scores we keep, and never show

We also calculate internal scores. How fast a post is growing. How memeable the AI thinks a story is. Whether a story has cleared the bar to appear at all. These are stored alongside everything else, and they are what decides which stories reach the feed and in what order — they are the reason the product works. They are *never* shown to a user and never sent to their browser. The app’s job is to make the judgement so the user does not have to. Publishing our workings would just hand them the job back.

STORED, USED TO DECIDE — STAYS ON OUR SERVERS			
NEVER LEAVES THE MACHINE · NEVER IN THE APP			
How fast it is growing — worked out from the view readings How memeable the AI judged it — and its reasoning Whether it clears the bar to appear — and why it was held back How sure we are a coin belongs to a story The order the feed should be in, and how that order changed			
SENT TO THE BROWSER — FACTS ABOUT THE WORLD			
TRUE WHETHER OR NOT INSIDOR EXISTS			
The two-liner — the story in plain English Views, age, who posted it, on which platform Market cap, liquidity, holders, price change Which coin came first, which is biggest, and when each was made What other traders wrote, and how big it was when they wrote it			
The test: if a number would still be true with Insider switched off, it can go on screen. If it only exists because we calculated it, it does not.			

The left column is the company. The right column is the product. Nothing crosses from left to right, in any screen, at any time.

What it costs

About **£5 a day, roughly £150 a month**. Reading social posts is by far the biggest line and the only one that scales with how hard we look — four pounds in five. The AI judging is a pound. The database and the hosting are genuinely free at this size, and stay free until we are considerably busier than we are on day one.

WHERE EVERY POUND GOES			
PER DAY · STEADY STATE			
READING SOCIAL POSTS · £4.00		AI · £1.00	
80%			20%
LINE	SHARE OF THE DAILY SPEND	PER DAY	PER MONTH
Reading social posts		£4.00	£120
the data reseller · rented, and capped			
AI judging		£1.00	£30
Claude, reading the fastest-growing posts			
Database	FREE TIER	£0.00	£0
holds all six kinds of record			
Hosting	FREE TIER	£0.00	£0
the app and the shareable story pages			
Total		£5.00	£150

The spending limits are hard, not advisory. Before every request to the data reseller or to the AI, the system checks what it has already spent today against the cap. If the cap is reached, collection **pauses until the next day** — the machine stops rather than quietly running up a bill overnight while nobody is watching. A runaway loop or a bad day of traffic costs us the rest of that day’s stories, which is annoying. It does not cost us a four-figure invoice, which is not.

THE DAILY CAP

OUR OWN METER — NOT A SCREEN ANY USER SEES

SPENT TODAY · READING SOCIAL POSTS

£3.42 / £4.50

76% of today's allowance at 18:40. Normal. The Collector keeps running on its usual couple-of-minute cycle.

SPENT TODAY · AI JUDGING

£1.18 / £1.50

Above 75%, so only the fastest-growing posts are sent to the AI for the rest of the day. At **100% the requests stop entirely** and resume at midnight.

Ceiling: £6.00 a day across both suppliers · £180 a month · reaching it pauses collection, it never authorises an overspend.

Two behaviours, not one. At three-quarters spent we get pickier about what is worth paying to judge. At fully spent we stop. Neither needs anyone awake to decide it.

PART THREE

How it comes together

Where the line between the two halves sits, one story followed all the way through, and the order we build in.

09	Where the line sits
10	One story, end to end
11	The build plan

09. Where the line sits

Part three is where the two halves of this document meet. Everything before this was the machine; everything after is the screen. Exactly one rule governs what is allowed to cross between them.

The rule is short. **Facts about the world go on screen. Our reasoning never does.** A view count is a fact — the post really has 2.4 million views whether or not Insidor was ever built. A market cap is a fact. So is the time a post went up, the name of the account that posted it, and how many people hold a coin. All of those existed before we looked and would carry on existing if we shut down tomorrow.

Our reasoning is a different kind of thing. When our system decides a story is worth showing, it is doing arithmetic: comparing one view count against the same post's view count twenty minutes earlier, weighing how many separate people posted about the same ferry captain, asking the AI how memeable the thing is and getting a number back. Those numbers are real and they matter enormously — they are how the ordering is decided — but they exist only because we invented them. They are our workings, and workings do not belong in front of a user.

In the founder's words: *"The app's job is to make the judgement so the user doesn't have to. Showing our workings would just make them do our job for us."* That is the whole argument. A trader opening Insidor at 09:13 has perhaps ninety seconds before the window closes. If we hand them a heat score of 8.4 and an acceleration ratio of 3.1x, we have not helped them decide — we have handed them a second decision on top of the first one, and asked them to learn our internal scale before they can use the product. The correct output of all that arithmetic is not a number. It is an ordered list and one plain sentence.

ON SCREEN	NEVER ON SCREEN
Facts about the world	Our reasoning
True regardless of Insidor. Anyone could verify them from the original post, the block explorer, or a price feed.	Exists only because we computed it. Meaningless outside our own system, and impossible for a user to check.
How many people have seen the post2.4M views	How memeable the AI scored it meme_score 7

 Still climbing

Buy \$FERRY

Same story, same underlying numbers, same ranking. On the left the user is asked to interpret five scales they have never been taught. On the right they are told what happened, how many people have seen it, how old it is, that one coin exists and it was the first, that attention is still going up – and given one button to act on it. Seven things, nothing else. The reasoning that produced that ordering is identical in both – only one of them says so out loud.

The harder cases

Obvious internals are easy to keep off screen. The rule earns its keep in the awkward cases, where a number would be genuinely convenient and still has to stay behind the curtain.

“A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back.”

@nordkyst_ferge on X · 2.4M views · 4h old

BEHIND IT three collectors, twelve re-measurements, one AI judgement, one grouping decision

A. FIRST, BIGGEST and UNVERIFIED are things the user can act on; 94% is a thing they'd have to interpret. B. A line that goes up says "still climbing" faster than any percentage, and cannot be misread as a promise. C. A disabled button is a taunt – it says we know something and won't tell you; showing nothing, plus a link out, is honest. D. The two-liner is not a summary of the reasoning, it *is* the reasoning, delivered.

The test

Any new screen, any new field, any argument about whether something belongs — this settles it in about five seconds, and anyone on the team can apply it without asking.

BEFORE YOU PUT A NUMBER ON SCREEN, ASK	
Would this number still be true if Insider did not exist?	
YES → IT CAN BE SHOWN	NO → IT STAYS BEHIND THE SCENES
2.4M views — the post has them either way	meme_score 7 — we invented the scale
\$799.6K — on-chain, public, checkable	accel 3.1x — needs our own history to exist
4h old — the clock is not ours	match 87% — our uncertainty, not theirs
1,204 holders — anyone can count them	rank ▲4 — a fact about our list, not the world

10. One story, end to end

One morning, minute by minute. This is the Harbor Last Horn story from Part One with the six-part machine from Part Two running underneath it, so you can see exactly which part was doing what, and when.

At 09:00 a Norwegian account called [@nordkyst_ferge](#) posts a clip. A retiring ferry captain blows his horn one last time, and every other boat in the harbour blows theirs back. It is a lovely forty seconds of video. Nobody in crypto is looking at it, because as far as crypto is concerned there is nothing there to look at — no coin, no chart, no money moving. Every tool a memecoin trader uses starts working at the moment money starts moving. On this particular morning, that moment is 09:47.

Insidor is looking at 09:04.

Seven moments, drawn to real time. Four of them happen inside nine minutes, which is why the leader lines fan the way they do — the cards are evenly spaced, the moments are not. The cyan band is the product. Everything below the line is the machinery from Part Two, running.

What the user actually did

Almost nothing, which is the point. At around 09:13 they opened Insidor while waiting for a coffee. Near the top of the feed was a card with one sentence on it — “A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back” — a still from the clip, the title *Harbor Last Horn*, the view count, a tiny line graph still bending upwards, how old it was, and one button reading **Create coin**, because nobody had made one yet. Seven things, exactly as in Section 2. Who posted it comes on the next screen, when they tap through.

They read the sentence, watched the clip, and decided the horn was funny enough that other people would find it funny too. That took about eighteen minutes of thinking about it and going back to it. At 09:31 they tapped **Create**. The tap opened pump.fun with a name and ticker already filled in and their wallet already connected through Privy, and **\$FERRY** existed. They were the first person in the world to make a coin out of that video. Sixteen minutes later the rest of crypto Twitter arrived and found a coin that was already there.

What was happening while they did it

At 09:04 **the Collector** did what it does every couple of minutes: asked our data reseller for posts pulling unusual attention right now. The ferry clip came back with 41,000 views. On its own that number means nothing — it could be a post that exploded in ten minutes or one that crawled there over two days.

So **the Measurer** put it on a list and looked at it again. At 09:09 the same post read 118,000 views. That second reading is the whole trick: two numbers on the same post five minutes apart is the difference between a story that is still climbing and one that is already over. Nobody will sell us that comparison later. If we are not writing it down as it happens, it is gone.

The Judge then read the post and answered one question — could a person realistically make a memecoin out of this? Most fast-growing posts fail that test: politics, sport, a plane crash. A retiring captain and a harbour full of horns passes it easily, and it comes with a name attached. At 09:12 a second clip of the same moment turned up on TikTok from a different account, and **the Grouper** tied the two together into one narrative. One person posting is luck. Two independent people posting the same moment is a meme forming.

Every reading, every judgement and both source posts went into **the Library** as they happened, which is why at 09:13 **the App** could put the story in front of every user with nothing missing. And it is why, months from now, this morning will be one row in the record that powers **Stage 7** — the last stage of the build plan in Section 11, the one that can finally answer “what happened to stories like this one”. It only works if we started writing the rows down today.

11. The build plan

Eight stages, in order. Each one has to work before the next one makes any sense — and the first one is not setup. It is the question the whole company rests on, and it comes before we write a line of the product.

The temptation with a plan like this is to start with the visible things: the feed, the page, the buttons. We are deliberately not doing that. Everything visible in this deck sits on top of a single assumption — that our system genuinely finds memeable stories early — and that assumption has never been tested. Every setting in the collector, every cut-off, every filter was an educated guess made by one person in a week. So the first stage tests the guess.

STAGE 0 · COMES FIRST · DAYS, NOT MONTHS

Prove it actually works

The method is to **work backwards**. Instead of asking "will our system find good posts?" and waiting to see, we take coins that **already did well over the last few days**, trace each one back to the viral post it came from, and then check our own records: **did we see that post, and how early?** The answer already exists in the data we have been collecting. We just have to go and look.

Then the harder half. What did the winners have in common — the kind of story, the platform it started on, the shape of the growth, the language it was in? And critically, the comparison group: **posts that went hugely viral and never became anything at all**. If the winners and the nothings look identical to us, we have no signal. If they look different, that difference is the product.

STEP ONE

Start at the end

List the coins that actually made money in the last few days. Real outcomes, not our opinions.

STEP TWO

Trace each one home

Find the post that started it. Then check whether it is in our records, and what time we first wrote it down.

STEP THREE

Compare against the nothings

Do the same for posts that went viral and died. The difference between the two piles is the thing we are selling.

Here is what the working file looks like. This is not a product screen — it is our own worksheet, the thing we sit and read on the Monday morning after the week's data has been collected. Nothing on it is an opinion. It is coins, posts, view counts and clock times.

STAGE 0 WORKSHEET — WORKING BACKWARDS					LAST 7 DAYS · 12 COINS TRACED	
THE COIN	PEAK	THE POST IT CAME FROM	POSTED	WE RECORDED IT	AHEAD OF THE COIN BY	
\$FERRY	\$799.6K	A retiring ferry captain blew his horn one last time, and every boat in the harbour blew back. @nordkyst_ferge on X · 2.4M views	09:00	09:04 · 41K views	27 min	
\$PIGEON	\$753.5K	A chess grandmaster lost to a pigeon and wrote an essay about it. @boardroomdaily on X · 1.1M views	14:12	14:19 · 63K views	43 min	
\$PLANT	\$562.8K	A grandmother has been watering a plastic plant for eleven years and nobody told her. @quietchaosclips on X · 850K views	07:40	07:46 · 29K views	25 min	
\$KETTLE	\$410.2K	A man's kettle whistles the first four notes of the national anthem. posted in Norwegian · 690K views	03:18	never recorded	missed	
\$TILE	\$288.4K	A bathroom tile that looks exactly like a disappointed landlord. started on TikTok · 1.3M views	21:05	never recorded	missed	
Traced back to a post we already had: 9 of 12 Median head start: 31 min Missed: 3 — two started on TikTok, one was not in English						

Everything in this table is a fact about the world — a coin, a post, a view count, a clock time. That is the whole point: the test has to be settled by evidence, not by our own opinion of our own system. And the three misses are the most useful rows on the page. They tell us exactly what to fix: widen to TikTok, stop filtering out non-English.

3.1M views · 5h A politician’s remark at a press conference No object, no character, no name. Nothing to draw.	2.8M views · 8h A last-minute goal in a league match Enormous audience, but it belongs to a club and a sport, not to the internet.	1.9M views · 3h A breaking news bulletin about a storm Serious. Nobody wants a coin about it, and nobody would buy one.
---	---	--

All three are bigger than \$FERRY was and none of them became anything. Size is not the signal. One absurd, nameable thing is — a frog called Gerald, a plastic plant, a ferry horn. Stage 0 is how we find out whether our system already knows that, or only we do.

Stage 0 does two more things while it is running. The code gets tidied and organised at the same time, so that stages 1 to 7 are built on a foundation somebody else could pick up. And every coin we trace, every post we match, every miss we write down becomes the **first rows of the dataset behind Stage 7** — the record of which viral posts became coins that made money. That record is the thing a competitor cannot buy, and it starts being written here.

Stages 1 to 7

THE STAGE	WHAT IT IS	DONE LOOKS LIKE
01 The narratives feed	The live list of stories the system is watching right now, ordered so the one most worth looking at sits at the top, refreshing on its own.	DONE WHEN Someone who does not work here opens it cold and finds something they want to act on, without being told what they are looking at.
02 The narrative page THE BIG ONE	One page per story, with its own web address, so it can be pasted into a group chat and opened by somebody who has never heard of Insidor.	DONE WHEN A stranger clicks a shared link, reads "a retiring ferry captain blew his horn one last time", and understands the story in five seconds.
03 Trading in the page	If a coin already exists for the story, buying and selling it happens on that page rather than in another app.	DONE WHEN A user buys \$HORN from the Harbor Last Horn page, without leaving, and the trade settles.
04 Create a coin	If no coin exists yet, the user makes one in a single tap — named, ticker suggested, live in seconds.	DONE WHEN A user turns a story with no coin into \$FERRY at 09:31, and is genuinely the first one in.
05 The thesis layer	Comments on narratives — traders posting why they think a story will or will not run, with their history attached.	DONE WHEN People come back to read the replies to something they wrote yesterday. That is the moment leaving gets expensive.
06 Search, watchlist, trending	Finding a story again, following one, and seeing what everybody else is looking at.	DONE WHEN A user can pull up yesterday’s Norway story from memory and be told when a narrative they follow starts moving.
07 What happened to stories like this THE PAYOFF	Each story shows what comparable ones did after they became coins. Not a prediction — a record of what actually happened before.	DONE WHEN A story at 850K views and two hours old can show what the last forty stories of that size and shape went on to do.

Stage 2 is marked because it is the stage that decides whether we grow. A page with its own address is how one trader shows a friend, and how a friend arrives without anyone paying for an advert.

How the stages depend on each other

Read left to right and each stage needs the one before it — there is no point building trading into a page that does not exist. The line most people miss is the long one underneath: Stage 7 is not a late idea, it is the harvest of a crop planted in Stage 0. If we do not start recording on day one, Stage 7 is simply not available later at any price.

Left to right is the order we build in. The dashed line is the reason we do not skip Stage 0 and come back to it: skipping it does not delay Stage 7, it deletes it.

THE ONE THING THAT HAS TO BE TRUE

Every feature in this deck assumes our system genuinely finds memeable stories early.

The beautiful narrative page, the coin list, the one-tap create, the comments, the watchlist — **all of it is worthless if what we surface is noise**. No amount of design rescues a feed full of things nobody would ever make a coin out of. There is no supplier to call and no feature to add that fixes it.

That is why Stage 0 comes first, and why we should not build deep until it is answered. It can be answered in **days, not months** — the data is already sitting in our own records — and both possible answers are useful.

IF THE SIGNAL IS REAL

We have **proof**, not a story — traced coins, timestamps, and a measured head start we can put in front of an investor or a first user.

IF THE SIGNAL IS NOT REAL

We find out **before wasting a month**, and the misses tell us precisely what to change — more platforms, more languages, different filters.

Either outcome is worth having. The only bad version of this plan is the one where we build stages 1 through 7 first and find out at the end.
